

Are subdeltoid bursitis and polymyalgia rheumatica preferences of COVID-19 vaccine?

COVID-19 vaccine became clear card life-saving medication. Due to over world vaccination a rate of prevalence and incidence of coronal infection is going to back down. However, we meet different side effects of the vaccine. Two cases of subdeltoid bursitis after COVID-19 vaccination discussed.

Keywords: COVID-19 vaccine • subdeltoid bursitis • polymyalgia rheumatica • corticosteroid therapy

Introduction

COVID-19 vaccine became clear card lifesaving medication [1]. Due to over world vaccination a rate of prevalence and incidence of coronal infection is going to back down. However, we meet different side effects of the vaccine [2,3]. It is not surprise. The vaccine has properties to induce immune reactions and protective antibody production is only a

part of them. Here there is first illustration. Medical sister 59 years old got second vaccine and 4 days later felt severe shoulder pain, swelling and limitation of motion. After first vaccination, there was only minor shoulder pain of the same side. Focus of injection (lateral shoulder) was not tender or red but a forward part of humeral head became swollen and painful. US showed pannus of

Figure 1. Anterior subdeltoid region, longitudinal view: Pannus of subdeltoid bursa (arrow).

Figure 2. Left, transverse subacromial anterior view: biceps tenosynovitis (arrow). Right, longitudinal coronal view: subdeltoid fluid due to bursitis (arrowhead). Thickened deltoid fascia (2 mm, Normal <1 mm) is marked.

subdeltoid bursa (Figure 1). Intrabursal injection with bethamethasone 6 mg followed by gradual pain, swelling and stiffness resolution during one week. Second history was graduate development of severe bilateral shoulder pain and stiffness in patients 83 years old for 3 weeks after second COVID-19 vaccination. Both injections performed on the same side. Severe subacromial tenderness, swelling and limitation observed. US showed bilateral tenosynovitis, subdeltoid bursitis and deltoid fasciitis (Figure 2) associated with polymyalgia rheumatica. C-reactive protein was elevated 35 times of normal. Methylprednisolone intravenous infusion

of daily dose 25 mg followed by prednisone 20 mg/day alleviated complaints by 70% during next 3 days.

COVID-19 vaccine has high immunogenicity. As result of poor antigen presentation or failed antibody response S-protein may expansively spread causing tissue damage and hypersensitivity reactions. Once upon ago an alternative mechanism of molecular mimicry was proposed [4]. Due to similarity of foreign antigen and host tissues, a process of neutralization of the antigen may be defected. This brings about its uncontrolled expansion and long standing autoimmune disease
